

## L15: Medium Access Control

Sebastian Magierowski  
York University

## Outline

---

- Multiple access communications
  - Taxonomy
  - Examples
- Simple efficiency calculations
- Random access: ALOHA
- Carrier sensing
- Collision detection

## Multiple Access Communications

- **Shared media** basis for broadcast networks
  - Inexpensive: radio over air; copper or coaxial cable
  - $M$  users communicate by broadcasting into medium
- Key issue: How to share the medium?

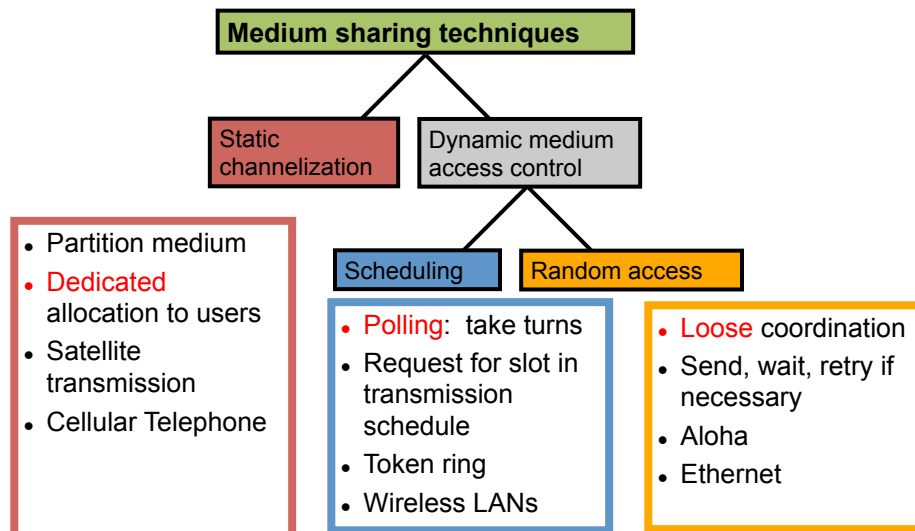

EECS 3213, F14

L15: Medium Access Control

3

## Approaches to Media Sharing

EECS 3213, F14

L15: Medium Access Control

4

## Channelization: Satellite

### Satellite Channel

EECS 3213, F14

L15: Medium Access Control

5

## Channelization: Cellular

$uplink f_1$  ;  $downlink f_2$

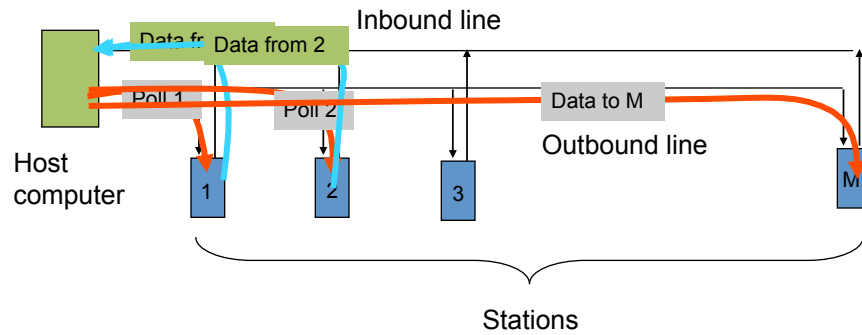

$uplink f_3$  ;  $downlink f_4$

EECS 3213, F14

L15: Medium Access Control

6

## Scheduling: Polling

## Scheduling: Token-Passing

## Random Access

- Multitapped Bus

- Transmit when read
- Transmissions can occur
- Need retransmission strategy

## Wireless LAN

- AdHoc: station-to-station
- Infrastructure: stations to base station
- Random access & polling

## Delay-Bandwidth Product

---

- **Delay-bandwidth** product key parameter
  - Coordination in sharing medium involves using bandwidth (explicitly or implicitly)
  - Difficulty of coordination commensurate with delay-bandwidth product
- Simple **two-station example**
  - Station with frame to send **listens** to medium and **transmits** if medium found idle
  - Station **monitors** medium to detect collision
  - If **collision** occurs, station that began transmitting earlier retransmits (propagation time is known)

## Two-Station MAC Example

---

- Two stations are trying to share a common medium

## Efficiency of Two-Station Example

---

- Each frame transmission requires  $2t_{prop}$  of quiet time
  - Station B needs to be quiet  $t_{prop}$  before AND after Station A's transmit
  - $R$  transmission bit rate
  - $L$  bits/frame

$$\text{Efficiency} = \rho_{\max} = \frac{L}{L + 2t_{prop}R} = \frac{1}{1 + 2t_{prop}R/L} = \frac{1}{1 + 2a}$$

$$\text{MaxThroughput} = R_{\text{eff}} = \frac{L}{L/R + 2t_{prop}} = \frac{1}{1 + 2a} R \text{ bits/second}$$

Normalized  
Delay-Bandwidth  
Product

$$a = \frac{t_{prop}}{L/R}$$

← Propagation delay  
← Time to transmit a frame

## Typical MAC Efficiencies

---

Two-Station Example:

$$\text{Efficiency} = \frac{1}{1 + 2a}$$

CSMA-CD (Ethernet) protocol:

$$\text{Efficiency} = \frac{1}{1 + 6.44a}$$

Token-ring network:

$$\text{Efficiency} = \frac{1}{1 + a'}$$

$a'$  = latency of the ring (bits)/average frame length

- If  $a \ll 1$ , then efficiency close to 100%
- As  $a$  approaches 1, the efficiency becomes low

## Typical Delay-Bandwidth Products

Distance	10 Mbps	100 Mbps	1 Gbps	Network Type
1 m	$3.33 \times 10^{-6}$	$3.33 \times 10^{-5}$	$3.33 \times 10^{-4}$	Desk area network
100 m	$3.33 \times 10^{-4}$	$3.33 \times 10^{-3}$	$3.33 \times 10^{-2}$	Local area network
10 km	$3.33 \times 10^{-2}$	$3.33 \times 10^{-1}$	$3.33 \times 10^{+0}$	Metropolitan area network
1,000 km	$3.33 \times 10^{+1}$	$3.33 \times 10^{+2}$	$3.33 \times 10^{+3}$	Wide area network
100,000 km	$3.33 \times 10^{+3}$	$3.33 \times 10^{+4}$	$3.33 \times 10^{+5}$	Global area network

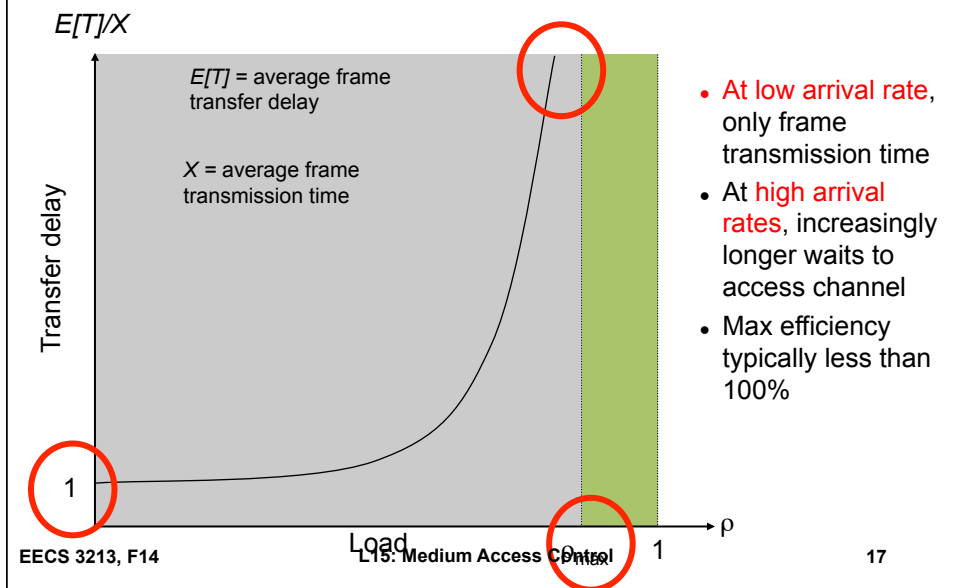

- **Max size** Ethernet frame: 1,500 bytes = 12,000 bits
- Long and/or fat pipes give large  $a$

## MAC Delay Performance

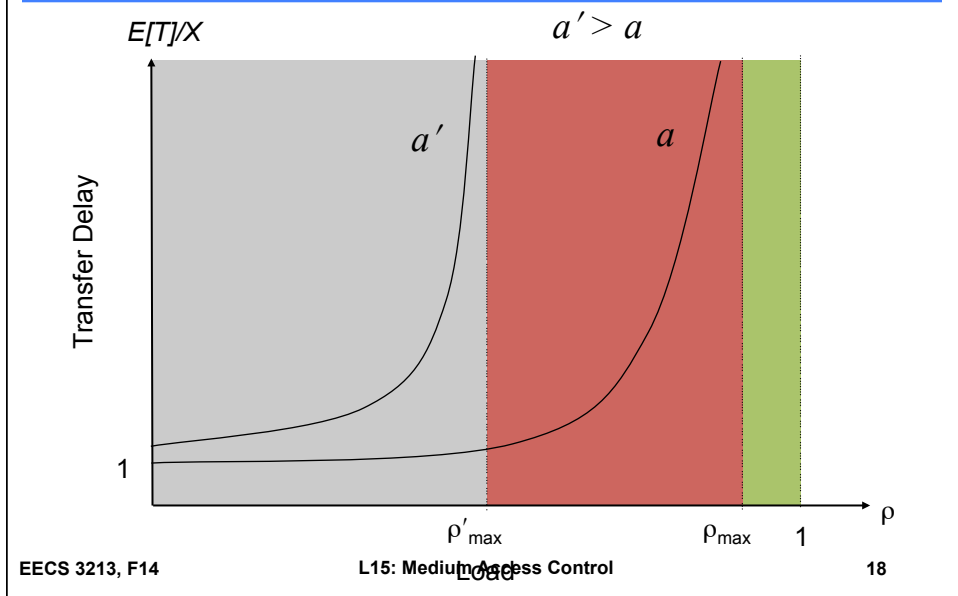

- Frame transfer delay
  - **From:** First bit of frame arrives at source MAC
  - **To:** Last bit of frame delivered at destination MAC
- Throughput
  - Rate at which signals successfully transmitted over medium
  - Measured in frames/sec or bits/sec
- Parameters
  - $\lambda$  avg. number of successfully transmitted frames/second
  - $R$  bits/sec &  $L$  bits/frame
  - $X=L/R$  seconds/frame (avg. time span of frame)
  - Carried Load:**  $\rho = \lambda X$ , (normalized throughput) (can't exceed 1)
  - Maximum throughput (@100% efficiency):  $R/L$  fr/sec

## Normalized Delay vs Load

## Dependence on $Rt_{prop}/L = a$

## ALOHA

- Wireless link to provide data transfer between main campus & remote campuses of University of Hawaii
- **Simplest solution:** just do it
  - A station transmits whenever it has data to transmit
  - If more than one frames are transmitted, they interfere with each other (collide) and are lost
  - If ACK not received within timeout, then a station picks random backoff time (to avoid repeated collision)
  - Station retransmits frame after backoff time

## ALOHA Model

- Definitions
  - $X$ : avg. frame transmission time (seconds)
  - $G$ : "total load" ("offered load"), rate at which NEW & RETRANSMITTED frames pumped into channel (frames/ $X$  seconds)
  - $S$ : "throughput"/"carried load", rate at which NEW info get successfully through channel (frames/ $X$  seconds)
  - $P_{success}$ : probability a frame transmission is successful

- Transmission successful if:
  - No OTHER transmission occurs during vulnerable period
  - vulnerable period is  $t_0 - X$  TO  $t_0 + X$

## Abramson's Assumption

- What is probability of no arrivals in vulnerable period?
- **Abramson assumption:** Effect of backoff algorithm is that frame arrivals are equally likely to occur at any time interval
- $G = \lambda \cdot X$  : avg. # arrivals per  $X$  seconds
- Divide  $X$  into  $n$  intervals of duration  $\Delta = X/n$
- $p$  = probability of arrival in  $\Delta$  interval, then
 
$$G = n \cdot p \quad (\text{since there are } n \text{ intervals in } X \text{ seconds})$$

$$P_{\text{success}} = P[0 \text{ arrivals in } 2X \text{ seconds}] =$$

$$= P[0 \text{ arrivals in } 2n \text{ intervals}]$$

$$= (1-p)^{2n} = \left(1 - \frac{G}{n}\right)^{2n} \rightarrow e^{-2G} \text{ as } n \rightarrow \infty$$

## Throughput of ALOHA

$$S = GP_{\text{success}} = Ge^{-2G}$$

- **Max carried load** is  $\rho_{\text{max}} = 1/2e$  (18.4%)
  - 18.4% of new frames launched per  $X$  get through network
- **Bimodal behaviour**
  - Small  $G$ ,  $S \approx G$
  - Large  $G$ ,  $S \downarrow 0$
- Collisions can snowball and drop throughput to zero

## Slotted ALOHA

- Time is slotted in  $X$  second slots
- Stations synchronized to frame times
- Stations transmit frames in first slot after frame arrival in data link transmit queue
- Backoff intervals in multiples of slots

*Only frames that arrive during prior  $X$  seconds collide*

## Throughput of Slotted ALOHA

$$S = GP_{success} = GP[\text{no arrivals in } X \text{ seconds}]$$

$$= GP[\text{no arrivals in } n \text{ intervals}]$$

## Carrier Sensing Multiple Access (CSMA)

- A station senses the channel before it starts transmission
  - If busy, either wait or schedule backoff (different options)
  - If idle, start transmission
  - Vulnerable period is reduced to  $t_{prop}$  (due to *channel capture* effect)
  - If  $t_{prop} > X$ , no gain compared to ALOHA or slotted ALOHA

EECS 3213, F14

L15: Medium Access Control

25

## CSMA Options

- Transmitter behavior when busy channel is sensed
  - 1-persistent CSMA (most greedy)
    - Start transmission as soon as the channel becomes idle
    - Low delay and low efficiency
  - Non-persistent CSMA (least greedy)
    - Wait a backoff period, then sense carrier again
    - High delay and high efficiency
  - p-persistent CSMA (adjustable greedy)
    - Wait till channel becomes idle, transmit with prob.  $p$ ; or wait one mini-slot time & re-sense with probability  $1-p$
    - Delay and efficiency can be balanced

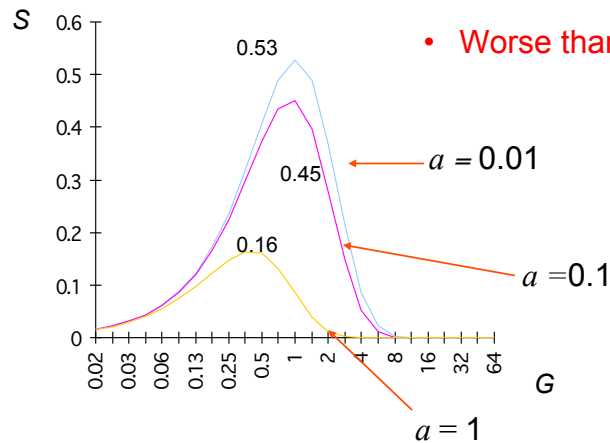

EECS 3213, F14

L15: Medium Access Control

26

## 1-Persistent CSMA Throughput

- Better than ALOHA & slotted ALOHA for small  $a$
- Worse than ALOHA for  $a > 1$

EECS 3213, F14

L15: Medium Access Control

27

## Non-Persistent CSMA Throughput

- Higher maximum throughput than 1-Persistent for small  $a$
- Worse than ALOHA for  $a > 1$

EECS 3213, F14

L15: Medium Access Control

28

## CSMA with Collision Detection (CSMA-CD)

- Monitor for collisions & abort transmission
  - Stations with frames to send, first do carrier sensing
  - After beginning transmissions, stations continue listening to the medium to detect collisions
  - If collisions detected, all stations involved stop transmission, reschedule random backoff times, and try again at scheduled times
- In CSMA collisions result in wastage of X seconds spent transmitting an entire frame
- CSMA-CD reduces wastage to time to detect collision and abort transmission

## CSMA-CD Reaction Time

*It takes  $2 t_{prop}$  to find out if channel has been captured*

## CSMA-CD Model

---

- Assumptions
  - Collisions can be detected and resolved in  $2t_{prop}$
  - Time slotted in  $2t_{prop}$  slots during contention periods
  - Assume  $n$  busy stations, and each may transmit with probability  $p$  in each contention time slot
  - Once the contention period is over (a station successfully occupies the channel), channel is busy and it takes  $X$  seconds for a frame to be transmitted
  - It takes  $t_{prop}$  before the next contention period starts

## Contention Resolution

---

- How long does it take to resolve contention?
- Contention is resolved (“success”) if exactly 1 station transmits in a slot:

$$P_{success} = np(1-p)^{n-1}$$

- Taking derivative of  $P_{success}$  we find max occurs at  $p=1/n$

$$P_{success}^{max} = n \frac{1}{n} \left(1 - \frac{1}{n}\right)^{n-1} = \left(1 - \frac{1}{n}\right)^{n-1} \rightarrow \frac{1}{e}$$

- On average,  $1/P^{max} = e = 2.718$  time slots to resolve contention

$$\text{Average Contention Period} = 2t_{prop} e \text{ seconds}$$

## CSMA-CD Throughput

- At maximum throughput, systems alternates between contention periods and frame transmission times

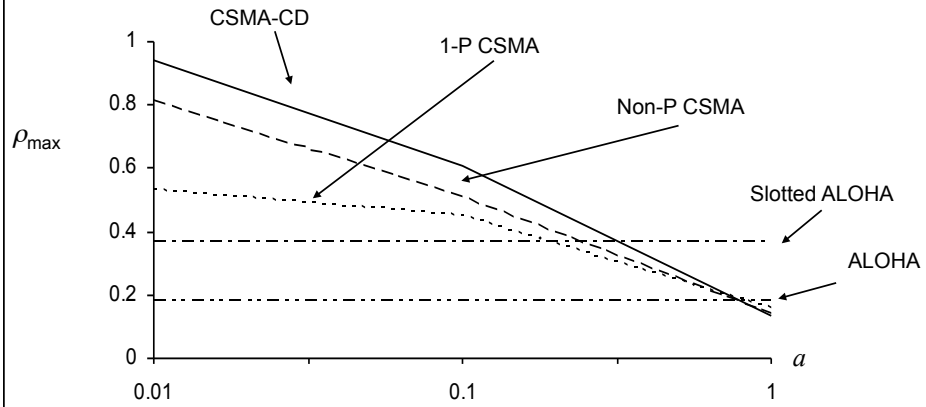

$$\rho_{\max} = \frac{X}{X + t_{prop} + 2et_{prop}} = \frac{1}{1 + (2e + 1)a} = \frac{1}{1 + (2e + 1)Rd / v L}$$

- where:
  - $R$  bits/sec,  $L$  bits/frame,  $X=L/R$  seconds/frame
  - $a = t_{prop}/X$
  - $v$  meters/sec. speed of light in medium
  - $d$  meters is diameter of system
  - $2e+1 = 6.44$

## CSMA-CD Application: Ethernet

- First Ethernet LAN standard used CSMA-CD
  - 1-persistent Carrier Sensing
  - $R = 10$  Mbps
  - $t_{prop} = 51.2$  microseconds
    - 512 bits = 64 byte slot
    - accommodates 2.5 km + 4 repeaters
  - Truncated Binary Exponential Backoff
    - After  $n$ th collision, select backoff from  $\{0, 1, \dots, 2^k - 1\}$ , where  $k = \min(n, 10)$

## Throughput for Random Access MACs

- For small  $a$ : CSMA-CD has best throughput
- For larger  $a$ : Aloha & slotted Aloha better throughput
