EECS 3213 Fall 2014

L5: Protocols, Services, Layers

Sebastian Magierowski York University

Outline

- Network Layering Terminology
 - protocols, services, peers, clients, etc.
- Network Protocol Examples
 - HTTP, TCP, DNS, UDP

Protocols

- For remote entities to establish working communications a set of rules needs to be in place
- Protocols are just these rules
 - HTTP
 - TCP
 - DNS
 - UDP
 - BGP
 - OSPF
 - etc., etc.,...
- In this lecture we look at some of these rules at work within the context of two other important ideas "layers" and "services"

EECS 3213, F14

5.1 Network Layers

- Network functions are complex and require careful design
- To reduce design complexity network functions are organized as a stack of layers

5.1 Network Layers

- Purpose of layer is to:
- 1. Provide "services" to layer above (e.g. routing, error control, connectionoriented link, etc.)
- 2. Shielding upper layers from implementation details (i.e. information hiding/abstract data types, etc.)

5.2 Layer Communication Flow

- "INTERFACE" lies between each pair of adjacent layers
- INTERFACE defines which services lower layers makes available to layer above

OSI Network Layers (A Preview)

L5: Protocol/Service/Layer

5.3 Peers and Protocols

• Corresponding layer on different machines are called

5.3 Peers and Protocols

 In ABSTRACT we think of virtual communication that happens between peers

- Communication between peers adheres to specific rules called protocols (e.g. HTTP)
- Protocols are implementations of a service

EECS 3213, F14

L5: Protocol/Service/Layer

5.4 Protocols In Action: Web Browsing

 I (client machine) want to grab a file (web page) from a server machine

• A whole bunch of rules (protocols) need to be followed to make this happen

5.4 Web Browsing

• At the top is HTTP

- In the abstract two HTTP entities are engaging in a virtual communication
 - The entities are using the HTTP protocol
 - Let's look at this in more detail...

5.5 HTTP

- To get a web page a specific set of rules is followed
 - Generally speaking HTTP is a "request-reply" protocol

• HTTP relies on the services of a bunch of other layers and their protocols...let's see this in even more detail!

EECS 3213, F14

5.6 DNS (Domain Name System)

- How does C (the client) know where to send its messages (exactly)?????
 - <u>www.nytimes.com</u> is actually the server's address
 - But machines work with a 32-bit address (IP address)
 - not an alphanumeric one

- So you need something capable of translating alphanumeric domain names to IP address
 - DNS does this
- A few words on IP address
 - Often written in "dot-decimal" notation (for our consumption)
 - 2 level-hierarchy
 - netID.hostID

L5: Protocol/Service/Layer

5.6 DNS

- In the end the DNS system runs the DNS protocol
 - It runs this on top of the UDP layer (which runs the UDP protocol)

5.7 TCP

 HTTP employs the services of a lower layer and its protocol: TCP

TCP Ports

• TCP can be serving a number of higher-level protocols simultaneously

- Define TCP (Transport) address which can identify different higher-level protocols
 - Ports
 - 16-bit number (64k possible ports)
 - First 1k are reserved (remainder are ephemeral)

HTTP Uses Service of TCP

5.8 TCP Communications

- TCP provides connection-oriented byte stream service
 - Makes sure destination is available and reserves our access to it until disconnect (Layer 4 virtual circuit)
 - Delivers the bytes that a message is made up of in order
- How? Labels messages with sequence numbers

SN2 AN2 B2 SN, AN, B, X SN2= Y, AN2= x+5, B2= 2 SN1= X+9, AN1= Y+3, B > PROBLEM !!! got $SV_1 = x + 9$, but expected x+5 L5: Protocol/Service/Layer

18

EECS 3213, F14

5.9 TCP Connection Establishment

• A 3-way handshake

SYN REQUEST	$SW, SN_{1}=\chi$	
	AN AN ANZ = 2+1	EVALLALY DEEDMILE
	5YN, 5N2-75 10-10	STIV/ACK RESPONSE
ACK REPLY	SN,= x+1, ACK, AN= y+1	n in anterne j
		connection acceptance

Predictable Sequence Numbers...

• ...can cause problems

SYN, SNI= n	Valla States
SUAL SN2=N, ACK, ANZENTI	was the same
< Squ je	
SN,=H+1, ACK, AND=H+1	\mathbf{N}
if SN,= n+2,	a delayed packet
AN,= N+2	might be accepted

5.10 TCP Hacks

• SYN Flood

SYN Cookies

Calculating SN's

SNs=y=f(IPe, porte, other param) ANc=y+1 if y+1=f(IPe, porte,...)=1 then ANe=y+1 is the correct ACK number

Man-in-the-Middle Attack
